### **description**

The TPA0233 is a 2-W mono bridge-tied-load (BTL) amplifier designed to drive speakers with as low as 4- $\Omega$ impedance. The mono signal is created by summing left and right inputs. The amplifier can be reconfigured on the fly to drive two stereo single-ended (SE) signals into head phones. This makes the device ideal for use in small notebook computers, PDAs, digital personal audio players, anyplace a mono speaker and stereo headphones are required. From a 5-V supply, the TPA0233 deliver 2 W of power into a 4-Ω speaker.

The gain of the input stage is set by the user-selected input resistor and a 50-kΩ internal feedback resistor  $(A_V = -R_F/R_I)$ . The power stage is internally configured with a gain of  $-1.25$  V/V in SE mode, and  $-2.5$  V/V in BTL mode. Thus, the overall gain of the amplifier is 62.5 kΩ/ R<sub>I</sub> in SE mode and 125 kΩ/ R<sub>I</sub> in BTL mode. The input terminals are high-impedance CMOS inputs, and can be used as summing nodes.

The TPA0233 is available in the 10-pin thermally-enhanced MSOP package (DGQ) and operates over an ambient temperature range of –40°C to 85°C.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

**Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.**

SLOS278D – JANUARY 2000 – REVISED NOVEMBER 2002

### **functional block diagram**

#### **AVAILABLE OPTIONS**

† The DGQ package are available taped and reeled. To order a taped and reeled part, add the suffix R to the part number (e.g., TPA0233DGQR).

SLOS278D – JANUARY 2000 – REVISED NOVEMBER 2002

#### **gain setting via input resistance**

The gain of the input stage is set by the user-selected input resistor and a 50-kΩ internal feedback resistor.

However, the power stage is internally configured with a gain of –1.25 V/V in stereo mode, and –2.5 V/V in mono mode. Thus, the feedback resistor (R<sub>F</sub>) is effectively 62.5 kΩ in stereo mode and 125 kΩ in mono mode. Therefore, the overall gain can be calculated using equations (1) and (2) stereo.

$$
A_V = \frac{-125 \text{ k}\Omega}{R_I} \quad \text{(Mono)}
$$
 (1)

$$
A_V = \frac{-62.5 \text{ k}\Omega}{R_I}
$$
 (Stereo) (2)

The –3 dB frequency can be calculated using equation 3.

$$
f_{-3 \text{ dB}} = \frac{1}{2\pi R_{\text{I}} C_{\text{i}}}
$$
 (3)

If the filter must be more accurate, the value of the capacitor should be increased while the value of the resistor to ground should be decreased. In addition, the order of the filter could be increased.

#### **input capacitor, Ci**

In the typical application an input capacitor  $(C_i)$ , is required to allow the amplifier to bias the input signal to the proper dc level for optimum operation. In this case, C<sub>i</sub> and the input resistance of the amplifier, R<sub>I</sub>, form a high-pass filter with the corner frequency determined in equation 4.

The value of C<sub>i</sub> is important to consider as it directly affects the bass (low frequency) performance of the circuit. Consider the example where R<sub>I</sub> is 10 kΩ and the specification calls for a flat bass response down to 40 Hz. Equation 2 is reconfigured as equation 5.

$$
C_{i} = \frac{1}{2\pi R_{i}f_{C}}
$$
 (5)

In this example, C<sub>I</sub> is 0.4  $\mu$ F so one would likely choose a value in the range of 0.47  $\mu$ F to 1  $\mu$ F. A further consideration for this capacitor is the leakage path from the input source through the input network (C<sub>i</sub>) and the feedback network to the load. This leakage current creates a dc offset voltage at the input to the amplifier that reduces useful headroom, especially in high gain applications. For this reason a low-leakage tantalum or ceramic capacitor is the best choice. When polarized capacitors are used, the positive side of the capacitor should face the amplifier input in most applications as the dc level there is held at  $V_{DD}/2$ , which is likely higher than the source dc level. Note that it is important to confirm the capacitor polarity in the application.

### **power supply decoupling, C(S)**

The TPA0233 is a high-performance CMOS audio amplifier that requires adequate power supply decoupling to ensure the output total harmonic distortion (THD) is as low as possible. Power supply decoupling also prevents oscillations for long lead lengths between the amplifier and the speaker. The optimum decoupling is achieved by using two capacitors of different types that target different types of noise on the power supply leads. For higher frequency transients, spikes, or digital hash on the line, a good low equivalent-series-resistance (ESR) ceramic capacitor, typically 0.1  $\mu$ F placed as close as possible to the device  $V_{DD}$  lead, works best. For filtering lower-frequency noise signals, a larger aluminum electrolytic capacitor of 10  $\mu$ F or greater placed near the audio power amplifier is recommended.

## **midrail bypass capacitor, C(BYP)**

The midrail bypass capacitor  $(C_{(BYP)})$ , is the most critical capacitor and serves several important functions. During start-up or recovery from shutdown mode,  $C_{(BYP)}$  determines the rate at which the amplifier starts up. The second function is to reduce noise produced by the power supply caused by coupling into the output drive signal. This noise is from the midrail generation circuit internal to the amplifier, which appears as degraded PSRR and THD+N.

Bypass capacitor (C<sub>(BYP)</sub>), values of 0.47-µF to 1-µF ceramic or tantalum low-ESR capacitors are recommended for the best THD and noise performance.

### **output coupling capacitor, C(C)**

In the typical single-supply stereo configuration, an output coupling capacitor  $(C_{(C)})$  is required to block the dc bias at the output of the amplifier, thus preventing dc currents in the load. As with the input coupling capacitor, the output coupling capacitor and impedance of the load form a high-pass filter governed by equation 6.

The main disadvantage, from a performance standpoint, is the load impedances are typically small, which drives the low-frequency corner higher, degrading the bass response. Large values of  $C_{(C)}$  are required to pass low frequencies into the load. Consider the example where a C<sub>(C)</sub> of 330  $\mu$ F is chosen and loads vary from 3  $\Omega$ , 4  $\Omega$ , 8  $\Omega$ , 32  $\Omega$ , 10 k $\Omega$ , to 47 k $\Omega$ . Table 1 summarizes the frequency response characteristics of each configuration.

### **output coupling capacitor, C(C) (continued)**

As Table 1 indicates, most of the bass response is attenuated into a 4- $\Omega$  load, an 8- $\Omega$  load is adequate, headphone response is good, and drive into line level inputs (a home stereo for example) is exceptional.

Furthermore, the total amount of ripple current that must flow through the capacitor must be considered when choosing the component. As shown in the application circuit, one coupling capacitor must be in series with the mono loudspeaker for proper operation of the stereo-mono switching circuit. For a 4- $\Omega$  load, this capacitor must be able to handle about 700 mA of ripple current for a continuous output power of 2 W.

#### **using low-ESR capacitors**

Low-ESR capacitors are recommended throughout this applications section. A real (as opposed to ideal) capacitor can be modeled simply as a resistor in series with an ideal capacitor. The voltage drop across this resistor minimizes the beneficial effects of the capacitor in the circuit. The lower the equivalent value of this resistance the more the real capacitor behaves like an ideal capacitor.

#### **bridged-tied load versus single-ended mode**

Figure 24 shows a Class-AB audio power amplifier (APA) in a BTL configuration. The TPA0233 BTL amplifier consists of two Class-AB amplifiers driving both ends of the load. There are several potential benefits to this differential drive configuration, but initially consider power to the load. The differential drive to the speaker means that as one side is slewing up, the other side is slewing down, and vice versa. This, in effect, doubles the voltage swing on the load as compared to a ground referenced load. Plugging  $2 \times V_{O(PP)}$  into the power equation, where voltage is squared, yields  $4\times$  the output power from the same supply rail and load impedance. See equation 7.

Power V(RMS) 2 RL (7) V(RMS) VO(PP) 2 2-**RL 2x VO(PP) VO(PP) –VO(PP) VDD VDD**

**Figure 24. Bridge-Tied Load Configuration**

#### **bridged-tied load versus single-ended mode (continued)**

In a typical computer sound channel operating at 5 V, bridging raises the power into an 8-Ω speaker from a singled-ended (SE, ground reference) limit of 250 mW to 1 W. In sound power, that is a 6-dB improvement which is loudness that can be heard. In addition to increased power, there are frequency response concerns. Consider the single-supply SE configuration shown in Figure 25. A coupling capacitor is required to block the dc offset voltage from reaching the load. These capacitors can be quite large (approximately 33  $\mu$ F to 1000  $\mu$ F) so they tend to be expensive, heavy, occupy valuable PCB area, and have the additional drawback of limiting low-frequency performance of the system. This frequency limiting effect is due to the high-pass filter network created with the speaker impedance and the coupling capacitance and is calculated with equation 8.

$$
f_C = \frac{1}{2\pi R_L C_{(C)}}
$$
 (8)

For example, a 68-µF capacitor with an 8-Ω speaker would attenuate low frequencies below 293 Hz. The BTL configuration cancels the dc offsets, which eliminates the need for the blocking capacitors. Low-frequency performance is then limited only by the input network and speaker response. Cost and PCB space are also minimized by eliminating the bulky coupling capacitor.

**Figure 25. Single-Ended Configuration and Frequency Response**

Increasing power to the load does carry a penalty of increased internal power dissipation. The increased dissipation is understandable considering that the BTL configuration produces 4× the output power of the SE configuration. Internal dissipation versus output power is discussed further in the crest factor and thermal considerations section.

### **single-ended (stereo) operation**

In SE (stereo) mode (see Figure 24 and Figure 25), the load is driven from the primary amplifier output for each channel (LO and RO, terminals 6 and 10).

The amplifier switches to single-ended operation when the  $ST/\overline{MN}$  terminal is held high.

### **input operation**

The input allows stereo inputs to be applied to the amplifier. When the ST/MN terminal is held high, the inputs (LIN and RIN) drive the outputs as LO and RO in stereo mode. When the ST/MN terminal is held low, the inputs are surrounded internally to create the mono BTL signal, driving the outputs as MO+ and MO–.

### **TPA0233 2-W MONO AUDIO POWER AMPLIFIER WITH HEADPHONE DRIVE** SLOS278D – JANUARY 2000 – REVISED NOVEMBER 2002

### **APPLICATION INFORMATION**

#### **BTL amplifier efficiency**

Class-AB amplifiers are inefficient. The primary cause of inefficiencies is the voltage drop across the output stage transistors. There are two components of the internal voltage drop. One is the headroom or dc voltage drop that varies inversely to output power. The second component is due to the sinewave nature of the output. The total voltage drop can be calculated by subtracting the RMS value of the output voltage from  $V_{DD}$ . The internal voltage drop multiplied by the RMS value of the supply current,  $I<sub>DD</sub>rms$ , determines the internal power dissipation of the amplifier.

An easy-to-use equation to calculate efficiency starts out as being equal to the ratio of power from the power supply to the power delivered to the load. To accurately calculate the RMS and average values of power in the load and in the amplifier, the current and voltage waveform shapes must first be understood. See Figure 26.

**Figure 26. Voltage and Current Waveforms for BTL Amplifiers**

Although the voltages and currents for SE and BTL are sinusoidal in the load, currents from the supply are very different between SE and BTL configurations. In an SE application the current waveform is a half-wave rectified shape, whereas in BTL it is a full-wave rectified waveform. This means RMS conversion factors are different. Keep in mind that for most of the waveform both the push and pull transistors are not on at the same time, which supports the fact that each amplifier in the BTL device only draws current from the supply for half the waveform. The following equations are the basis for calculating amplifier efficiency.

Efficiency of a BTL amplifier = 
$$
\frac{P_L}{P_{SUP}}
$$
 (9)

where

$$
P_{L} = \frac{V_{LRMS}^{2}}{R_{L}}, \text{ and } V_{LRMS} = \frac{V_{P}}{\sqrt{2}}, \text{ therefore, } P_{L} = \frac{V_{P}^{2}}{2R_{L}}
$$
  

$$
P_{SLIP} = V_{DD} I_{DD} \text{avg} \qquad \text{and} \qquad I_{DD} \text{avg} = \frac{1}{\pi} \int^{\pi} \frac{V_{P}}{P} \sin(t) dt = \frac{1}{\pi} \times \frac{V_{P}}{R} [\cos(t)] \frac{\pi}{0} = \frac{2V_{F}}{\pi R}
$$

and 
$$
P_{SUP} = V_{DD}I_{DD}avg
$$
 and  $I_{DD}avg = \frac{1}{\pi} \int_0^{\pi} \frac{V_P}{R_L} \sin(t) dt = \frac{1}{\pi} \times \frac{V_P}{R_L} [\cos(t)]_0^{\pi} = \frac{2V_P}{\pi R_L}$ 

therefore,

$$
P_{SUP} = \frac{2 V_{DD} V_P}{\pi R_L}
$$

substituting  $P_1$  and  $P_{SUP}$  into equation 9,

Efficiency of a BTL amplifier 
$$
= \frac{\frac{V_{p}^{2}}{2 R_{L}}}{\frac{2 V_{DD} V_{p}}{\pi R_{L}}} = \frac{\pi V_{p}}{4 V_{DD}}
$$

where

$$
V_{\mathsf{P}} = \sqrt{2 P_{\mathsf{L}} R_{\mathsf{L}}}
$$

### **BTL amplifier efficiency (continued)**

therefore,

$$
\eta_{\text{BTL}} = \frac{\pi \sqrt{2 P_{\text{L}} R_{\text{L}}}}{4 V_{\text{DD}}}
$$

(10)

 $P_L$  = Power devilered to load  $P_{SUP}$  = Power drawn from power supply  $V_{LRMS}$  = RMS voltage on BTL load  $R_L$  = Load resistance

 $V_P$  = Peak voltage on BTL load  $I_{DD}$ avg = Average current drawn from the power supply  $V_{DD}$  = Power supply voltage  $\eta_{\text{BTL}}$  = Efficiency of a BTL amplifier

Table 2 employs equation 10 to calculate efficiencies for four different output power levels. Note that the efficiency of the amplifier is quite low for lower power levels and rises sharply as power to the load is increased, resulting in a nearly flat internal power dissipation over the normal operating range. Note that the internal dissipation at full output power is less than in the half power range. Calculating the efficiency for a specific system is the key to proper power supply design. For a stereo 1-W audio system with 8-Ω loads and a 5-V supply, the maximum draw on the power supply is almost 3.25 W.

† High peak voltages cause the THD to increase.

A final point to remember about Class-AB amplifiers (either SE or BTL) is how to manipulate the terms in the efficiency equation to utmost advantage when possible. Note that in equation 10,  $V_{DD}$  is in the denominator. This indicates that as  $V_{DD}$  goes down, efficiency goes up.

#### **crest factor and thermal considerations**

Class-AB power amplifiers dissipate a significant amount of heat in the package under normal operating conditions. A typical music CD requires 12 dB to 15 dB of dynamic range, or headroom above the average power output, to pass the loudest portions of the signal without distortion. In other words, music typically has a crest factor between 12 dB and 15 dB. When determining the optimal ambient operating temperature, the internal dissipated power at the average output power level must be used. The TPA0233 data sheet shows that when the TPA0233 is operating from a 5-V supply into a 4-Ω speaker, 4-W peaks are available. Converting watts to dB:

$$
P_{dB} = 10 \text{Log} \frac{P_W}{P_{ref}} = 10 \text{Log} \frac{4 W}{1 W} = 6 dB \tag{11}
$$

Subtracting the headroom restriction to obtain the average listening level without distortion yields

 dB  $-$  15 dB  $=$   $-9$  dB (15-dB crest factor) dB  $-$  12 dB  $=$   $-6$  dB (12-dB crest factor) dB  $-$  9 dB  $=-3$  dB (9-dB crest factor) dB  $-$  6 dB  $=$  0 dB (6-dB crest factor) dB  $-$  3 dB  $=$  3 dB (3-dB crest factor)

### **crest factor and thermal considerations (continued)**

Converting dB back into watts:

$$
P_{W} = 10^{PdB/10} \times P_{ref}
$$

- 63 mW (18-dB crest factor)
- $= 125$  mW (15-dB crest factor)
- 250 mW (9-dB crest factor)
- 500 mW (6-dB crest factor)
- 1000 mW (3-dB crest factor)
- $= 2000$  mW (15-dB crest factor)

This is valuable information to consider when attempting to estimate the heat dissipation requirements for the amplifier system. Comparing the absolute worst case, which is 2 W of continuous power output with a 3-dB crest factor, against 12-dB and 15-dB applications drastically affects maximum ambient temperature ratings for the system. Table 3 shows maximum ambient temperatures and TPA0233 internal power dissipation for various output-power levels.

<b>PEAK OUTPUT POWER</b> (W)	<b>AVERAGE OUTPUT POWER</b>	<b>POWER DISSIPATION</b> (W)	<b>MAXIMUM AMBIENT</b> <b>TEMPERATURE</b>
	2 W (3-dB crest factor)		$-3$ °C
	1000 mW (6-dB crest factor)	1.6	$6^{\circ}$ C
	500 mW (9-dB crest factor)	1.4	$24^{\circ}$ C
	250 mW (12-dB crest factor)		$51^{\circ}$ C
	125 mW (15-dB crest factor)	0.8	78°C
	63 mW (18-dB crest factor)	0.6	$96^{\circ}$ C

**Table 3. TPA0233 Power Rating, 5-V, 3-**Ω**, Mono**

**Table 4. TPA0233 Power Rating, 5-V, 8-**Ω**, Stereo**

The maximum dissipated power (P<sub>Dmax</sub>), is reached at a much lower output power level for an 8- $\Omega$  load than for a 4-Ω load. As a result, this simple formula for calculating P<sub>Dmax</sub> may be used for a 4-Ω application.

$$
P_{Dmax} = \frac{2V_{DD}^2}{\pi^2 R_L}
$$

(13)

However, in the case of a 4- $\Omega$  load, the P<sub>Dmax</sub> occurs at a point well above the normal operating power level. The amplifier may therefore be operated at a higher ambient temperature than required by the  $P_{Dmax}$  formula for a 4- $\Omega$  load.

The maximum ambient temperature depends on the heat sinking ability of the PCB system. The derating factor for the DGQ package is shown in the dissipation rating table. Converting this to  $\Theta_{JA}$ :

$$
\Theta_{JA} = \frac{1}{\text{Derating Factor}} = \frac{1}{0.0171} = 58.48 \text{°C/W} \tag{14}
$$

(12)

#### **crest factor and thermal considerations (continued)**

To calculate maximum ambient temperatures, first consider that the numbers from the dissipation graphs are per channel so the dissipated power needs to be doubled for two channel operation. Given Θ<sub>JA</sub>, the maximum allowable junction temperature, and the total internal dissipation, the maximum ambient temperature can be calculated with the following equation. The maximum recommended junction temperature for the TPA0233 is 150°C. The internal dissipation figures are taken from the Power Dissipation vs Output Power graphs.

$$
T_A \text{ Max } = T_J \text{ Max } - \Theta_{JA} P_D = 150 - 58.48(0.8 \times 2) = 56^{\circ}C (15 \text{-dB crest factor})
$$
\n(15)

#### **NOTE:**

Internal dissipation of 0.8 W is estimated for a 2-W system with 15-dB crest factor per channel.

Tables 3 and 4 show that for some applications no airflow is required to keep junction temperatures in the specified range. The TPA0233 is designed with thermal protection that turns the device off when the junction temperature surpasses 150°C to prevent damage to the IC. Tables 3 and 4 were calculated for maximum listening volume without distortion. When the output level is reduced the numbers in the table change significantly. Also, using 8- $\Omega$  speakers dramatically increases the thermal performance by increasing amplifier efficiency.

#### **ST/MN (stereo/mono) operation**

The ability of the TPA0233 to easily switch between mono BTL and stereo SE modes is one of its most important cost saving features. This feature eliminates the requirement for an additional headphone amplifier in applications where an internal speaker is driven in BTL mode but external stereo headphone or speakers must be accommodated. When ST/MN is held high, the RIN and LIN inputs drive the output as Lo and Ro in stereo SE mode. When ST/MN is held low, the inputs are summed internally and the output is driven as Mo+ and Mo– in mono BTL mode. Control of the ST/MN input can be from a logic-level CMOS source or, more typically, from a switch-controlled resistor divider network as shown in the functional block diagram.
